

WP10 – T10.4 – UC10.4 Industrial Inspection

ZG3D - Parellelization of an industrial inspection system

Abstract

- A comparison beetwen a sequential and a parallel model of the work performed at the inspection system to build a 3D representation of any digitized object is presented.
- The Use Case is based on a task of **3D object reconstruction** used in an industrial inspection framework to distinguish different objects and to find surface defects based on texture comparison.
- Modelled "Application Software" with one periodic flow representing the sequential and the parallel execution tasks of the reconstruction process. Modelled "Execution Platform" as 16 cores (two processors with 8 cores each one) to host the task set software model.
- Implemented optimization to exploit coarse- and fine-grain parallelism of the reconstruction process to take advantage of multi-core execution platforms.
- Execution times of each task have been measured and added to the application model. The art2kitekt tool suite provides a Minimal Response Time analysis for sequential and parallel execution of the modelled application.

Application Software

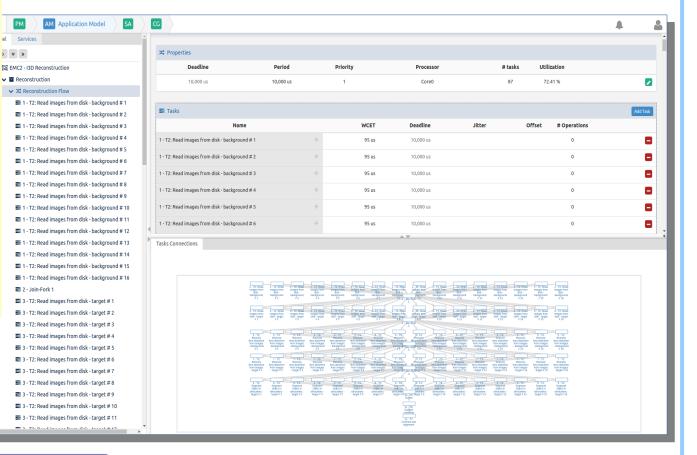

Execution Platform

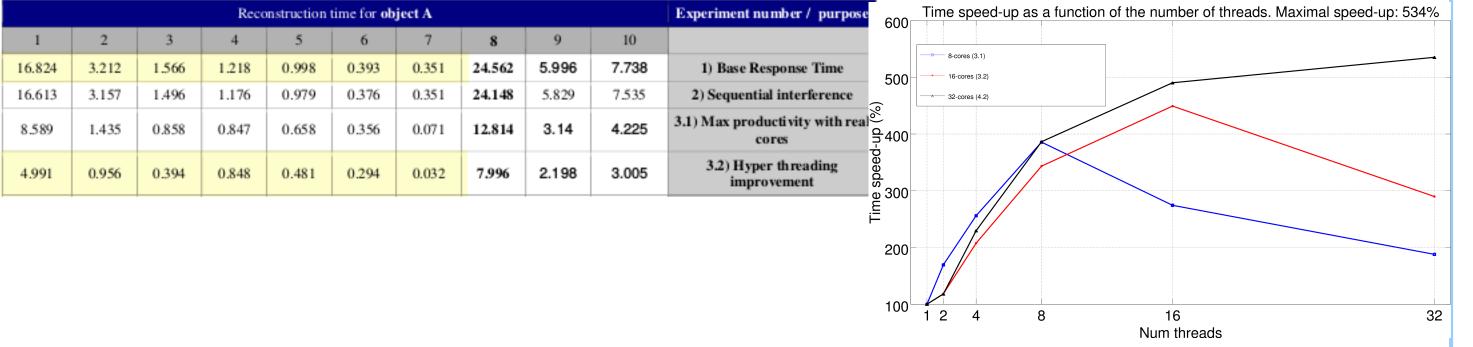

Memorie

Devices

Buses

- One flow to model the application software: parallel tasks (1 to 4) and common tasks (5 to 7).
- 1 Load cameras number and calibration: Reading sub-process accessing disk storage.
- 2 Reading images from disk: Equivalent to the previous "Load distorted background/target images" sub-process also accessing disk storage.
- 3 Remove lens-object distortion from images: Equivalent to the previous "Undistort background/target images" computation intensive sub-process.
- 4 Segment silhouettes: Another step of the intensive computation process.
- 5 Octree computing: The most performance requiring stage and heavily parallelized with OpenMP directives.
- 6 Surface marching cubes computing: This subtask cannot be parallelized, and thus it is carried out once every octree computation has finished.
- 7 Centroid and alignment: Again, this task cannot be parallelized and it is initiated after the "Surface marching cubes computing".

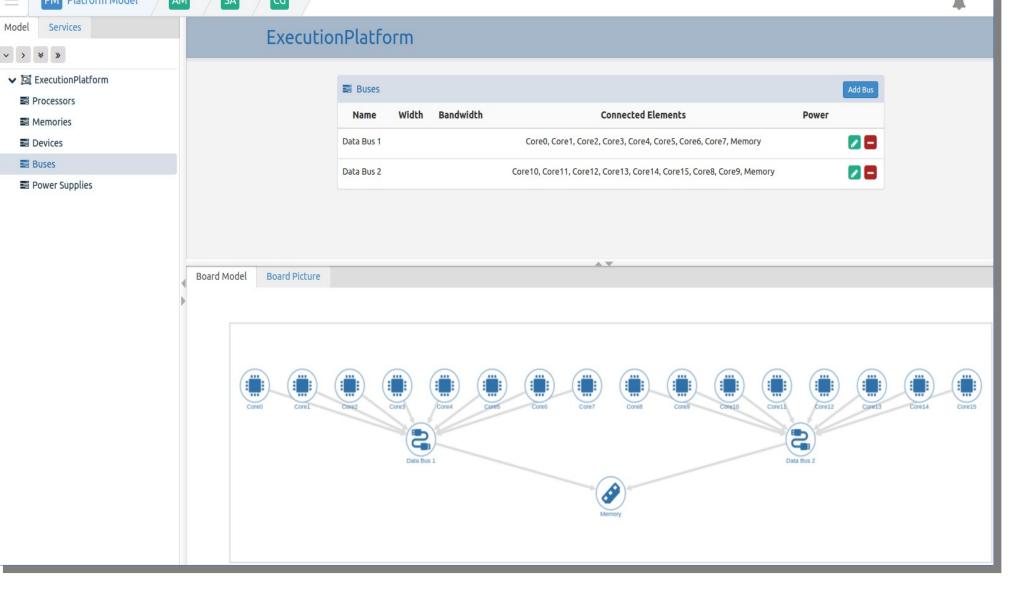

3D reconstruction time saving according to number of cores (see time VS cores). Steps 3,4,5,6,7 are considered.

System Analysis - MRT

- A multi-core execution platform has been predefined, with 2 processors, 16 cores and multithreading capabilities. PM Platform Model AM SA
- Implemented parallelism into single and double object reconstruction.

Reconstructed 3D object

- The objective of the Use Case is to compare between sequential and parallel models for a task of **3D** object reconstruction.
- The set of **images acquired from 16 cameras** are processed to build a 3D model of any object digitized by the inspection system.
- The implemented **Minimum Response Times** algorithm is fast enough to be executed "on the fly". The engineer is able to manually test several possible options and see the result immediately.

	Task			Sequential Execution			Parallel Execution								
Flow		Priority	WCET (us)	Response Time (us)		Feasible	Response Time (us)	Feasible	Deadline (us)	Period (us)

- An increased overall inspection performance has been achieved with OpenMP parallelization over the previously described execution platform.
- **Reduction of** computation time in a roughly **500%** has been achieved by exploiting coarse parallelism (detailed results at D10.4, section 5) and thus decreasing **latency**.

Conclusion

- A tool suite named art2kitekt developed as an integrated software tool for designing and analyzing mixed criticality, real-time systems has been applied to perform the modeling and off-line analysis for a given hardware platform and software task set, with high performance demand.
- An engineeering process of design and analysis guided by the tool has been performed. A set of parallel tasks aimed to reconstruct a 3D object have been optimized to perform as fast as possible on a virtual multi-core execution platform.
